

Preliminary Analyses:

To determine the possible association between intellectual humility and apology quality a Pearson's r correlation was conducted. The results found a statistically significant, moderate positive correlation $r(104) = .37, p < .001$.

Primary Analyses:

Next, we examined the effects of intellectual humility and post-transgression response on apology quality. To test this, we conducted a 2 (offense type: high intellectual humility vs. low intellectual humility) x 2 (post-transgressional response: forgiving vs. not forgiving) between-subjects ANOVA. Inconsistent with our hypothesis, there was no statistically significant main effect of intellectual humility on apology quality ($F = 0.52, p = .473$). Participants in the intellectual humility condition ($M = 5.08, SD = 0.94$) did not report higher quality apologies compared to participants in the control condition ($M = 4.93, SD = 1.11$). Additionally, inconsistent with our second hypothesis, there was no statistically significant main effect of post-transgressional response on apology quality ($F = 0.22, p = .644$). Apologies from participants who did receive a forgiving post-transgressional response ($M = 4.94, SD = 0.92$) did not significantly differ from participants who did not receive a forgiving response ($M = 5.04, SD = 1.18$). Lastly, contrary to our third hypothesis, there was not a statistically significant interaction between intellectual humility and post-transgressional response on apology quality ($F = 0.06, p = .815$). Our results found that there wasn't a statistically significant difference in apology quality when intellectual humility was manipulated, when post-transgressional response was manipulated, and when both variables were manipulated.
