Expected Results

1. Background & Importance

Intellectual Humility (IH):

The ability to recognize that one's own beliefs and knowledge may be wrong.

Antisocial Personality Disorder (ASPD):

Characterized by an inconsideration for others and a lack of remorse.

Research has shown that IH predicts apology quality (Ludwig et al. 2022) —> Individuals with ASPD rarely admit wrongdoing

Previous Research

Intellectual Humility (IH) can be manipulated.

Ludwig et al. (2022) demonstrated temporary increases in IH

Intellectual Humility is a prosocial behavior.

Antisocial Personality Disorder is characterized by low prosocial tendencies

Can we model prosocial behaviors successfully

Effect of behavioral modeling and social influence on ASPD (Mazza et al (2025)

2. Research Question

- *Does observing intellectually humble behavior actually increase the chances of someone admitting to wrongdoing?*
- *Will individuals with ASPD be able to encode the modeling of behavior?*
- *Does the severity of an individual's ASPD traits influence the effect of the modeling?*

Does modeling intellectual humility influence admission of wrongdoing in individuals with antisocial personality disorder?

Hypotheses

#1: Participants exposed to modeled IH will show greater admission of wrongdoing than those in the control condition.

#2: Participants diagnosed with ASPD will be less likely to admit to wrongdoing than participants without ASPD

#3: The effect of IH manipulation on admission of wrongdoing will differ depending on the participants' diagnosis of ASPD

3. Study Design - IV/DV

IV 1: Intellectual Humility (Modeling Behavior)

Level 1: Manipulated Positive

Level 2: Control (no modeling)

IV 2: Antisocial Personality Disorder

Level 1: Participants with a clinical diagnosis of ASPD

Level 2: Control -> Participants with no ASPD

DV: Admission of wrongdoing

Self-reported measures of wrongdoing and intellectual humility

Sample Population

- Adults ages 18 - 50 that are either diagnosed with ASPD or do not have ASPD
- Pulled from clinical settings and community samples

2 x 2 Between-Subjects design

- | | |
|---------------------------|------------------------------|
| ● ASPD with IH modeled | ● ASPD without IH modeled |
| ● No ASPD with IH modeled | ● No ASPD without IH modeled |

Methods

1. Participants are accepted either as ASPD or Control
2. Participants assigned to either control or manipulated group

Methods cont.

3. Participants are invited into the lab room where a “partner” (confederate) is waiting.
4. The researcher gives the pair a rigged cognitive assignment to work on together
5. The participant is then led to another room and asked to complete a self report on admission of wrongdoing and an intellectual humility scale (Porter & Schumann, 2018)

5-item self-report

1	How did you perform in accordance with your expectations? (1 - 7 scale)
2	How challenging did you find the task? (1 - 7 scale)
3	How satisfied were you with your own performance? (1 - 7 scale)
4	How satisfied were you with your partner's performance? (1 - 7 scale)
5	a) If you successfully completed the task: Who do you think contributed more to the completion of the task? (me/my partner) b) If you failed to complete the task: Who do you think contributed more to the failure of the task? (me/my partner)

5. Expected Results

Main Effect #1	Main Effect #2	Interaction Effect
Mean admission of wrongdoing in the IH condition > Mean admission of wrongdoing in the control condition	Mean admission of wrongdoing for people diagnosed with ASPD < Mean admission of wrongdoing for people without ASPD	The positive manipulation of Intellectual humility will be stronger for participants without ASPD

Thanks for Listening!
